看護学部・教授 木下 真里	マイノリティや社会的弱者の健康・生活情報の把握・活用方法に関する研究 -誰も取り残さない社会の実現を目指して-	R3-R4	500,000

研究概要

本研究は、在留外国人、高齢者、障がい者、路上生活者、LGBTQ、感染症キャリアなどマイノリティや社会的弱者の、健康状態や生活状況などの情報を、氏名や住所、マイナンバー、出身地などの個人情報と切り離してデータベースに記録・保存し、公的機関や支援関係者間で共有する、新しい仕組みの開発を目的とする。この新しい仕組みが実現すれば、個人情報利用の同意取得が困難な事情のある人々の実態把握が容易となり、持続可能な開発目標（SDGs）の共通理念「だれも取り残さない」の実現を通して、複数のSDGの実現に貢献できる。

研究では、個人情報の代わりに、一人ひとりに無償で配布する固有のQRコードによって個人を識別する。日本語でのコミュニケーションが十分でない外国人とICTになじみのない高齢者に、固有のQRコードを配布して定期的に追跡を行い、何人の対象者がいつまで把握できるかを調査することによって、この仕組みの効果と実用可能性を検証するアクション・リサーチである。また、この調査で収集した個別のデータを自治体、支援団体と共有することにより、実際に活用できるかどうかを検証する。

研究 成 果

研究者らは、大規模災害時、迅速に人的被害の全体像を把握する COACHES と呼ばれる仕組みの開発を行っている。本研究では、在留外国人や高齢者などマイノリティや社会的弱者を対象に、個人の権利を守りながらどのように安全、効果的にこの仕組みを活用できるかを明らかにすることを目的とした。専用アプリケーションを用いてこの仕組みを説明し、意見や感想を Focus Group Discussion (FGD) で聞き取るという研究である。

高齢者調査については、COVID-19 第 6 波、7 波および役場担当者の交代などを背景に、当初予定していた中山間部での同意取得が難航し、2 か所の候補地いずれからも協力辞退があり、実現しなかった。一方で、太平洋沿岸部に位置する地区については、先方から協力の連絡があり、令和 4 年に住民を対象とした調査が実施できた。

外国人調査については、プロジェクト期間を通して情報収集に努め、各学部プロジェクトメンバーからの専門的情報提供をもとに検討を続けた。最終的に、市内の外国人が集まる飲食店での調査可能性を数か月にわたって検討したが、プロジェクト終了までに責任者への説明機会が得られず、実施を断念した。

本研究プロジェクトの取組みによる成果は以下の通り。

- ・ SDGs の基本理念「誰も取りのこさない」を災害救援において実現するために、災害時にすべての被災者の安否、健康状態情報収集する仕組みの有用性および今後の課題があきらかになったこと。
- ・ 地域特性による災害に対する備えや新しい技術に対する人々の受入れの違いに関する知見。
- ・ 研究成果の学際的、国際的な発信。
- ・ 良好な学部間協力が実現し、学際的連携の実績となったこと。

¹University of Kochi Faculty of Nursing, Kochi, Japan, and ²Kochi University of Technology, Tosa Yamada, Kochi, Japan

Abstract: Objectives: The study's aim is to identify the challenges in estimating personal damages in the early stages of a disaster. Methods: The study reviewed personal damage data in the reports on the Great East Japan earthquake and tsunami published by Japanese public agencies from 2011 to 2020, including 159 situation reports by the Fire and Disaster Management Agency and 17 disaster-related indirect death reports by the Reconstruction Agency. The study compared the reported number of deaths, missing persons, and injuries with the latest statistics to evaluate how soon the disaster's personal damages were estimated. Results: The reported number of deaths significantly increased in the first 1.5 years, whereas the number of missing persons spiked in the first 30 days. It required approximately 1 year until the numbers approximated the current reference rate. The total casualties included 1739 indirect deaths. Conclusions: The results indicated an overestimation of missing persons, a possible underestimation of injuries, and the excess deaths due to indirect causes that complicated the estimation. The limitations of the current data collection approaches and the delay in reporting from the field and incomplete and unreliable information. A novel system is proposed, which directly collects data from all affected individuals asynchronously.

Introduction

It is essential to understand the complete impact of a disaster in order to provide adequate relief. If an event's scale is significant, it is crucial to have such information available, but it is challenging to assess the situation correctly and quickly. Therefore, relief workers usually do not attempt to fully enumerate the affected population and rather seek alternative approaches.¹ Researchers have experimented with various methods to measure the overall impact of disasters. Morgan et al. estimated Hurricane Sandy's (2012) damage in the United States by hospital admission records gathered from a public database, which captured 97% of hospital discharges in the area.² However, such an approach may not be suitable for quick estimates, with a "lag of 1–2 years" and incomplete coverage of discharges in the country. Meanwhile, Lee et al. conducted another study of post-tsunami Aceh, Indonesia, employing a cross-sectional survey design.³ It is undoubtedly necessary to have a comprehensive assessment in the early phases of the disaster, but it required specialized personnel and training.

Concerning Japan, a disaster-prone country, it has become common to prioritize vulnerable populations in search and rescue in an emergency, based on previous studies that highlighted the specific needs of vulnerable populations.⁴ It is also a legal obligation of the local government to list vulnerable populations in their community as part of their contingency plans.^{5,6} Such local administrative office defines vulnerability in disasters based on the information available in pre-disaster times, such as level of care for disability, elderly care insurance coverage, and intractable disease patient registration. However, the priority list may not be sufficiently helpful, as the local authorities usually do not update this information with the community until the very last minute of evacuation, for pre-emptive protection.⁷ Additionally, the list may not reflect actual conditions of the authorities do not regularly update the information on conditions because few people's conditions are stable, and changes may occur at any time.

Moreover, the approaches mentioned above compromise on covering the entire population to provide more efficient relief. Although such strategies are helpful, they exclude a vast majority

Disaster Medicine and Public Health Preparedness

of the affected population who do not complain or do not have a significant history of health problems but are certainly in need of assistance.

Further, permanent residents are usually not the only population affected by a disaster. There are visitors or tourists who, by chance, become involved in the accident. If a visitor is missing, injured, or sick, that person may not be immediately sought and rescued because of little information available to authorities aside from pre-disaster information.

The Great East Japan earthquake disaster (GEDJED) with GEDJED number (EQ-2011-000028) hit Japan's pacific coast on March 11, 2011, killing over 19 000 and leaving 2500 persons missing.⁸ The disaster reconstruction agency reported 1700 disaster-related indirect deaths by the end of March 2020.⁹ Approximately 30% of the 1620 indirect deaths reported by August 2012 were caused by "physical and mental conditions after spending some time at shelters" and 13 cases were suicides. Further analysis of 1263 cases in the high mortality area suggested that 10% of the cases had no previous history of illness, and 30% had an unknown past health history. The fact that the health history of 40% of indirect death cases was not recognized suggests that either some might have pre-incident to be in good health or people did not care about or notice their health condition until they died.

This study identified the challenges of measuring the disaster-affected population's health conditions by reviewing reports of personal damages published by governmental agencies in the 9 years after the GEDJED. The study then further discusses the significance of approaches by which to collect individual data directly from the affected population, not only from a specific group of people but also from most people considered to be in good health but who potentially need help.

Methods

The study reviewed 159 situation reports, from the second to the tenth in the first report to be publicly available, published by the Fire and Disaster Management Agency (FDMA) of the Ministry of Internal Affairs and Communications (MHA). There are many other official reports published by the government. The National Police Agency (NPA) report statistics on personal damages, consisting of original and revised data, throughout the post-disaster period. The self-defense force (SDF) deployed its search and rescue units until March 11, 2011, mainly for the first 8 days of the emergency phase. They issued their reports, but only a limited number of reports are available.

A series of FDMA situation reports published from March 11, 2011, to March 10, 2020, with the title of "平成23年(2011年)東日本大震災被害調査報告書(東日本大震災被災者)13" Report on 2011 Tohoku-Pacific Ocean Earthquake (GEDJED) or variations of these were selected, as they were considered more appropriate for the study purpose. The FDMA situation reports cover comprehensive information collected by local governments and are available from the early disaster response stages. While many other FDMA reports and papers were published, this specific series was selected to provide the necessary information for this study.

The number of deaths, missing persons, and injured persons (deaths + missing + injured) was analyzed based on the data from the disaster, gross mortality (deaths per 100 000 people), and total mortality (injuries per 100 000 people) calculated from the population census data in 2010 (the year before the disaster). The study reviewed the

2057

reports of disaster-related indirect deaths (Sagaku Kinensu 580) published by the Japanese disaster recovery agency to support our findings.¹⁰ A value of 18 549 was obtained by subtracting non-direct mortality (n = 1738, September 30, 2011) from the sum of the latest number of dead and missing persons (n = 22 288, March 10, 2020), assuming that the value represents the actual direct mortality due to the disaster. Then, an evaluation was made of how soon the true number of casualties could have been estimated using the FDMA statistics.

The data processing and statistical analysis used Microsoft Excel and StatCrunch 16.1 (College Station, TX) to conduct Poisson regressions, tests of proportions, and logistic regressions. The study adopted the following logistic regression models to estimate the odds of reporting injuries.

Logit(odd(Y = 1)) = β₀ + β₁X₁ + β₂X₂ + β₃X₃

Where Y = status of reporting injuries: 1 = failed, 0 = reported
X₁ = deaths per 100 000 populations reported in the 2010 census
X₂ = evacuation orders: 1 = given, 0 = not given
The variables were selected manually from the available data to provide the best fit.

Results

As of July 1, 2020, the FDMA had published 159 situation reports on its website.¹¹ The earliest available is the second report,¹² dated March 11, 2011, at 15:30 Japan Standard Time (JST), 44 minutes after the major earthquake. The latest is the 160th report,¹³ published on March 10, 2020.

FDMA released an update every half an hour for the first 5 hours and every hour until the end of the day. There were 11 issues of the report on Day 1 (1–4), March 11, 2011, followed by 11 on the following day (5–15), March 12, 2011. The FDMA issued updates daily until the end of April 2011 (Table 1).

Overview of Personal Damages in the Study Period (March 2011 to March 2020)

There were 14 240 affected with a Japanese scale of 1 or greater for 9 years,¹⁴ and the reported personal losses included the victims of those earthquakes. Some fractures were observed, particularly in the number of missing persons within 1 year of the disaster. The statistics became stable in and after 2012 (1 year after the first earthquake and series of tsunami). There have been no significant error reported in the past 9 years (Figure 1a).

The incidence of deaths increased by 27% daily in the first 2 weeks of the disaster (incidence rate ratio [IRR] = 1.27, P < 0.0001). The inflection slowed down after a final spike in September 2012 (IRR = 1.00, P < 0.0001). There was a spike in the number of missing persons in the first 30 days (IRR = 1.07, P < 0.0001), but the number dropped by Day 30 and continued to decrease (IRR = 0.99, P < 0.0001). There was a significant increase in mortality in the initial months (IRR = 1.05, P < 0.0001). Later, the increase slowed down significantly (IRR = 1.00, P < 0.0001) (Figure 2).

Figure 1b. (Continued)

When Was the Earliest Possible Timing for Estimating the Scale of Personal Damage?

The sum of deaths and missing persons reached the estimated total direct casualties (P_{td}) only on Day 11 (Report 67 of 68, n = 18313 or n = 1835, March 13, 2011). However, it was technically impossible to predict the scale of personal damage because the value continued to increase far beyond the threshold. The second possible opportunity to predict total direct casualties was at approximately Days 30–40, when the number of missing persons became stable and before indirect deaths started to increase. Under the assumption that there were no other causes of death other than the disaster, the number of missing persons reduced as the number of deaths increased (the number of disappearance of human remains). However, while the number of discovered deaths increased, the number of missing persons did not decrease at the same rate. Although there were thousands of after-shocks, including 11 earthquakes over M7.0 on the Richter scale,¹⁶ there were few casualties. Therefore, it is likely that there was another factor underlying the increased number of deaths, and disaster-related

indirect deaths are likely responsible. The disaster-related indirect deaths of survivors appeared to have caused a prolonged increase in mortality and made personal damage prediction more difficult.

Lack of Information

To reduce the number of indirect deaths and effectively use health professionals' efforts, it is necessary to know the health status of persons affected by a disaster. According to the reconstruction agency, among the 1262 disaster-related deaths observed in the first year of the disaster, 1229 (96.9%) appeared to be caused by physical or mental fatigue or stress.¹⁷ Although little is known about the factors that cause indirect deaths, data on the affected population's mental health conditions, for example, will be necessary as some indirect deaths were suicide cases. However, information on the affected population's mental health status is usually unavailable, as the current system does not collect this information routinely. If one could assess the general health status of the affected population, some of these deaths could have been prevented.

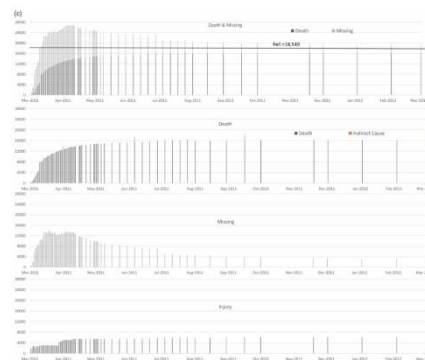

Figure 1c. (Continued)

Likewise, the current public system collects limited information on most people's health status, as injury is not a required field when applying for public financial aid for disaster victims under the Basic Act for Disaster Management. The Japanese culture also prevents people from complaining about their health conditions, as many Japanese people share social values of patience, keeping silent, and sacrificing themselves to save others. Therefore, collecting health information is proposed for all affected populations, including those undocumented persons who do not make health-related claims, and who are therefore considered in good health by default.

Are Data Reliable?

Overestimation of Missing Persons
An excess of missing persons for 1 month after the disaster was detected. There are 2 primary reasons: (1) Persons were dead but they had not been confirmed, or (2) persons were alive, but they failed to contact family due to confusion. Both reasons were likely responsible for the early spike in the number of missing

persons. According to the NPA statistics, the body identification rate was low (42.2% of 1986 bodies in the first 1 day).¹⁸ Their unactive efforts improved capacity in 1 month (83.6% of 13 951 dead bodies), but it required months to achieve identification of over 90% of bodies. Miscommunication is more likely responsible for the first increase in missing persons because it significantly decreased after 1 month. A joint operation among agencies for verification found a large number of double counts. Additionally, the closure of some shelters and the opening of temporary housing started, which increased the chances of reuniting separated families.

Underestimation of Injuries

The number of reported injuries was much smaller than the number of deaths. A possible explanation for the reduced number of injured persons is either high fatality rates or underreporting of injuries. The impact of earthquakes and tsunamis was extreme, and few people were able to survive. Further, some of the affected towns failed to report injuries, particularly among severely affected

Figure 2. Differences in the number of deaths, missing persons, and injuries from the previous report.

Figure 3. The range of reported numbers of indirect deaths (n=1000).

What is the Next Step?
To enable early estimation of total casualties in disasters, it is necessary to know the precise number of missing persons and indirect deaths that cause confusion of casualty estimates. The University of Kochi's team, in collaboration with the Kochi University of Technology, proposed a novel health assessment system (Figure 4) named *Community Oriented Approach for Comprehensive Health-care in Emergency Situation* (COACHES). It collects individual health data anonymously and records such data in a cloud-based database. The system runs on any personal mobile device (iPhone, iPad, Android) by scanning a personal identification code (QR code), distributed to every person in the area at multiple points during a disaster. The code is the only item used to identify an individual. The system does not require any prior training or application download, as this system's intended use will be in unpredictable emergencies.

It is expected that residents with qualifications in health care, such as nurses, will run this system as volunteers, with the idea that they are ready to work during an evacuation. They do not need extra training because they have the necessary professional skills and knowledge and local knowledge (such as where the people live, names of places, or local language) to minimize the lag in the wait for external relief. The idea is that someone first checks their family's health status then proceeds to their neighbors and produces as many records as possible. If the assessments and data collection occur in multiple places, the system will eventually cover the entire affected population. By standardizing each volunteer's assessment, the cloud-based database will provide helpful comprehensive information. External relief persons can take over the task as soon as they arrive so that local volunteers can return to their homes and families for reconstruction.

Table 2. Towns that failed to report the number of injuries and numbers of actual deaths and missing persons in those towns last of March 2003

Prefecture	Town	Deaths	Missing
Iwate	Shimizuwamura	1098	205
	Aburahi	924	130
	Chirai	856	412
	Tanaka	687	186
	Yamagata	953	470
Miyagi	Kanemitsu	2174	214
	Tagajo	218	0
	Yamagata	781	17
	Shimada	78	2
	Osakabe	614	257
	Yamagata	426	211
	Yamagata	442	8
Fukushima	Tomaru*	145	0
	Utsunomiya	178	37
	Maui	33	31
	Maui	48	1
	Hama	48	1

Note: *Towns within 50 km range of the Fukushima-Daiichi Nuclear Power Plant.

Figure 4. Flow of community-oriented approaches for comprehensive health care in emergency settings (COACHES).

The data recorded in the cloud database would be shared among relief workers, health workers, and government officials to improve the efficacy, quality, and coverage of relief activities. The system requires a strict verification process to connect the database with any personal information other than a unique QR code for individuals. The details of the system will be discussed in future correspondence.

Conclusion

The study's findings depict how challenging it is to collect reliable public health data in times of disaster. A significant delay in reporting was not reported, but there was an overestimation of missing persons and possible underreporting of injuries. These findings explain the limitations of existing approaches to health assessment

in extreme emergencies. Therefore, early and continuous evaluation of the whole affected population's health conditions is necessary to reduce preventable deaths from disaster-related factors. Thus, comprehensive approaches that enable reliable health assessment and provision of records of the entire community in emergencies are proposed, such as COACHES, to achieve the concept of UNSDGs, "Leaving no one behind."

Impact Objectives

- Investigate healthcare risks in complex humanitarian emergencies
- Develop a Community Oriented Approach for Comprehensive Healthcare in Emergency Situations (COACHES) to detect the healthcare needs among disaster-affected populations

Real-time data help disaster response

Disaster relief expert Professor Mari Kinoshita outlines her work as part of a team determining the specific healthcare needs of communities affected by natural disasters

You have been working in disaster relief for many years. How did your become inspired to lead this field?

Before I began working at the University of Kochi in 2019, I developed extensive experience working in the area of international public health with government organisations, Non-Governmental Organisations and an UN agency (UNHCR). Throughout this part of my career, I spent a significant amount of time and energy working on disaster relief and emergency relief activities. When I moved into my current position, it was the beginning of an attempt to pass on a legacy of my work to the next generation by codifying the lessons I have learned from my time in the field.

Generally, what type of research are you carrying out at the University of Kochi?

I am involved in a mixture of different research, including cross-sectional field studies that are mostly targeting people in the community. Usually, I start with qualitative research followed by a questionnaire survey. Action research is ongoing to develop a system to detect the healthcare needs among disaster-affected populations, while my cross-sectional

research activities are designed to detect healthcare risks in complex humanitarian emergencies.

From your perspective, what is the ultimate impact of your studies?

Ultimately, relief work during disasters will become more effective and efficient as a result of our work. This benefits all parties for obvious reasons, but the disaster-affected population as a whole will be the major beneficiaries.

Can you talk about some of the challenges you had to address through this research?

Finding a local partner agency for applying collaborative research funds has been the biggest challenge - we missed several funding opportunities due to being unable to find local business partners. Some companies have shown interest in the projects, but very few of them participated in the bidding. In relation to the COVID-19 pandemic, the demand for communication services is increasing and the IT business is booming. However, the local private company involved lacks the human resources necessary for this project.

What type of reactions have you had to your research from the community?

We had two different types of reactions from the communities and the local governments. Enthusiastic and supportive reactions full of suggestions are from individual government officers and residents in the coastal area where large-scale disaster damage is warned by the government. Mild and conservative reactions tend to be from the residents in the inland communities, where the risk of disaster is not high or localised. A similar reaction is observed in an official comment from the local government agencies, regardless of the location.

Finally, what are your plans for the next stages of this research?

The main priority is expanding the collaborations we are engaged with. More specifically, we want to work with private sectors for technical solutions, local governments for field testing and community involvement, and research partners in different academic fields to facilitate a multidisciplinary approach. In a few years, we will develop a practical model and proceed with field testing in real disaster situations. At this point we hope to make a real difference to the lives of people and communities affected by disasters. www.impact.pub

Coverage of COACHES

Helping Japanese communities affected by natural disasters

A team based at the University of Kochi in Japan is conducting research that seeks to develop a Community Oriented Approach for Comprehensive Healthcare in Emergency Situations (COACHES). The findings will help to provide more efficient and optimised relief to those affected by emergencies and disasters

Japan has a high prevalence of natural disasters. There are several reasons why this is so, including the weather resulting from Japan belonging to the Asian monsoon climate region; its terrain - with some 70 per cent of Japan's land mass being covered by mountains or hills; and urban development - where because of population growth and urbanisation, the non-mountainous areas in Japan are often expanded through reclaiming coastal areas. However, the location of Japan is arguably the most important reason why natural disasters occur so often when compared to other countries and regions around the world. Given all of this, it is essential that local and national governments, as well as other organisations, develop effective means of

handling the impacts of disasters and the emergencies that are a direct result from these.

THE WHOLE PICTURE

It is with this in mind that a research team with faculty members from different fields at two universities has embarked on its current studies. The team is led by Professor Mari Kinoshita, who has helped to propose a system known as the Community Oriented Approach for Comprehensive Healthcare in Emergency Situations (COACHES). It is hoped that through research and development, COACHES will be implemented across Japan and lead to more effective and efficient responses to the effects of disasters and emergencies.

Kinoshita describes how currently neither public agencies nor relief workers start organising emergency relief with real-time and reliable information about the disaster-affected population. She says they usually count on an estimation based on data collected in the past or unreliable information reported by non-professionals through a variety of sources, and they do not attempt to fully enumerate the affected population as they do not have proper measures available. "There are attempts to collect information by self-reporting systems, but they may fall some of the urgent needs because some are ignorant of their conditions, or some are uncomfortable reporting their conditions too urgently," explains Kinoshita. As a consequence, relief

efforts give priority to larger, visible and the closest populations." The COACHES project is designed to detect hidden or missed data and provide a whole picture of the situation to be able to provide more optimised relief.

DATA WITHOUT COMPROMISING PRIVACY

Put simply, COACHES works by providing information to relief personnel that is vital in an emergency situation. Importantly, it provides data on where the affected people are located, but also how they are doing at the present time. This enables the rescue and relief teams to determine a list of

of promise so far and once it has been fully developed it will provide a much-needed solution. There are some technical challenges that need to be overcome to make the system feasible and cost-effective, specifically damage to communication infrastructure and power supply disruption. "The power supply can be manageable by batteries and generators, but for the communication networks, we need collaboration with partners that are capable of providing communication technologies during disasters and emergency situations," outlines Kinoshita. "Another challenge is how to find volunteers in the disaster-

because they will play a leading role in introducing the system to their respective communities. It will only be through using the system that people gain confidence in it, so success is expected to snowball in the future. www.impact.pub

Mari Kinoshita is a professor of disaster and international nursing. She advances programmes and research that improves quality of care in complex emergencies and relief of affected populations in the community. Kinoshita's research interests include rapid health assessment, healthcare risks in disasters, refugee healthcare and community level infectious disease care.

"This anonymous system reduces the time and risks of data collection, thereby providing peace of mind to individuals and encouraging them to use the system."

priorities in terms of who requires attention urgently and those who might be able to wait a little longer. "The system records everyone's data so that it can be viewed later and analysed; this facilitates a process of continuous improvement, where responses can be fine-tuned and made better for the next incident," observes Kinoshita. "The system directly collects data from all affected individuals on an anonymous basis.

During a disaster, data-collecting volunteers check the health conditions of those around them, including themselves, their families, neighbours and anyone they meet on the way to the evacuation shelter. This information is then recorded on an exclusive database using a web-based application which is then shared among public and private agencies and rescue organisations to check the real-time situation. For the protection of privacy, the COACHES system does not collect personal identity, but instead, an individual is identified by scanning the personal identification codes with the data collector's mobile devices," highlights Kinoshita. "The QR codes will be distributed by local authorities with the help of community volunteers to every individual in a disaster-affected area. This anonymous system reduces the time and risks of data collection, thereby providing peace of mind to individuals and encouraging them to use the system," she says.

TOGETHER EVERYONE ACHIEVES MORE. As it stands, the system is currently still in the planning phase and therefore cannot yet be tested in a real-life situation. However, the research has shown a huge amount

affected community in an early phase of an emergency, especially given that the system heavily relies on volunteers. The essential part of the system does not run and cover the whole area without volunteers for the distribution of personal ID (QR) codes and data collection," she comments.

Despite these challenges, Kinoshita and the team are confident that with the help of members of society and various collaborative efforts they will soon be able to overcome the present hurdles and deploy a system that helps individuals and communities who are affected by disasters. Indeed, they believe that the public sector needs to be involved from an early stage
